

ITSS SOFTWARE DEVELOPMENT

## 6. CLASS DESIGN

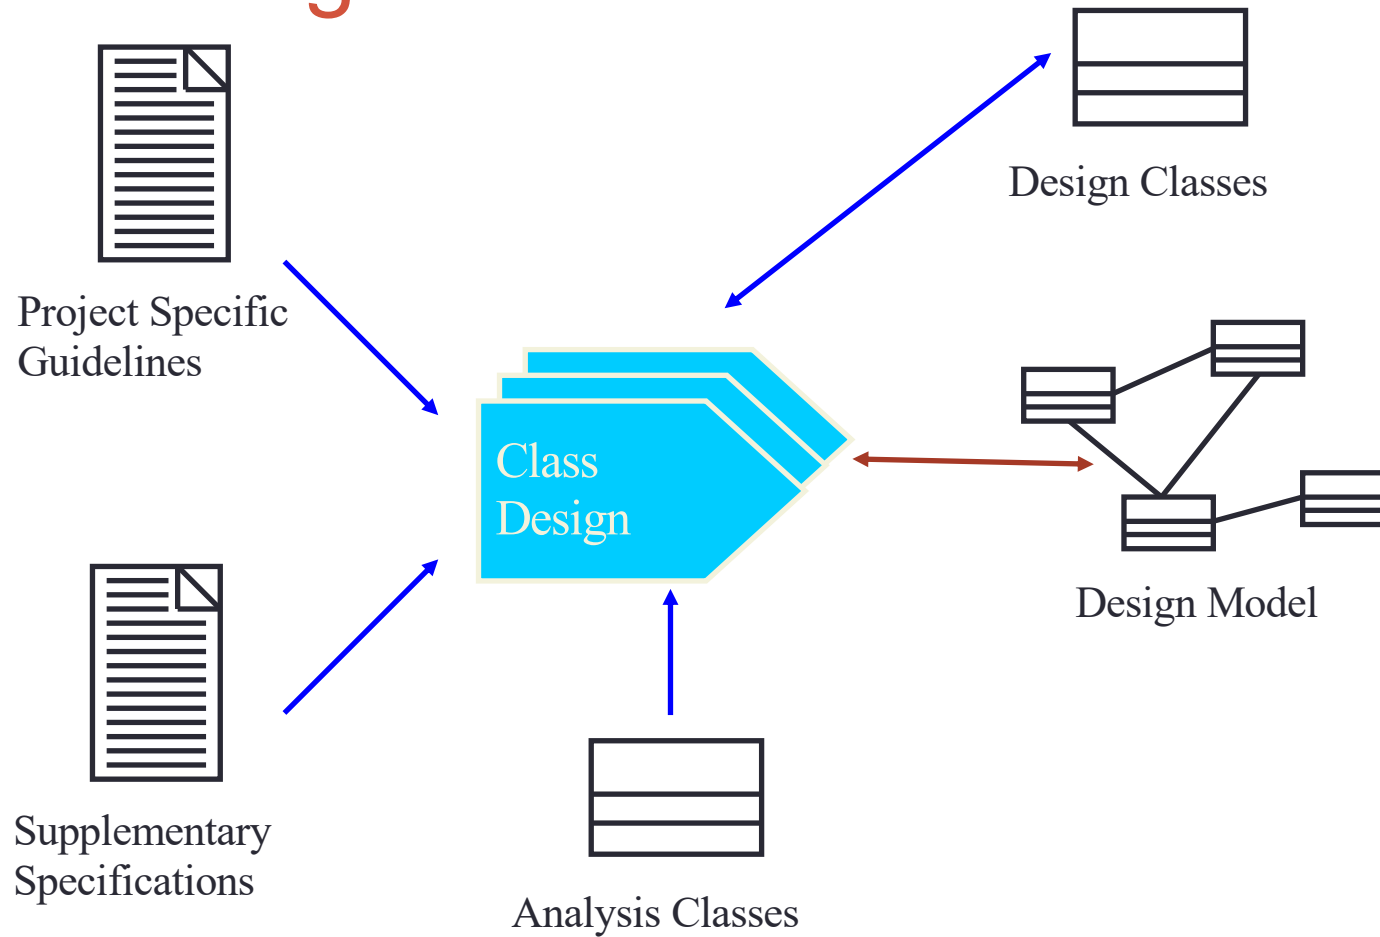

---

Nguyen Thi Thu Trang  
trangntt@soict.hust.edu.vn

*Some slides extracted from IBM coursewares*

# Class Design Overview

# Content

1. Create Initial Design Classes

2. Define Operations/Methods

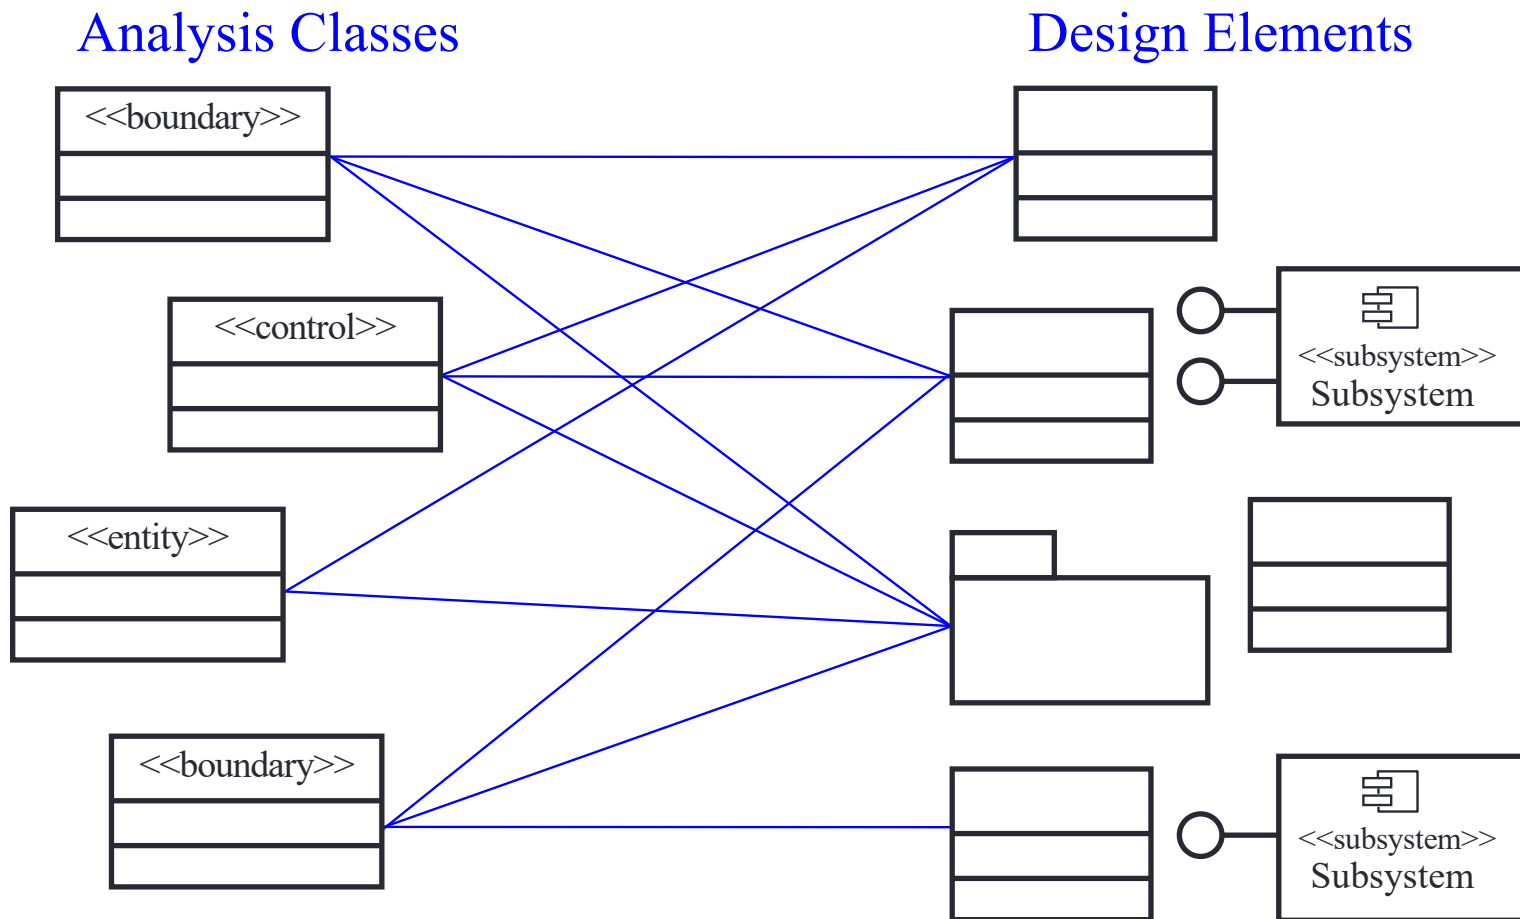

3. Define Relationships Between Classes

4. Define States

5. Define Attributes

6. Class Diagram

# From Analysis Classes to Design Elements

# Identifying Design Classes

- An analysis class maps directly to a design class if:
  - It is a simple class
  - It represents a single logical abstraction
- More complex analysis classes may
  - Split into multiple classes
  - Become a package
  - Become a subsystem (discussed later)
  - Any combination ...

# Class Design Considerations

- Class stereotype
  - Boundary
  - Entity
  - Control
- Applicable design patterns

## How Many Classes Are Needed?

- Many, simple classes means that each class
  - Encapsulates less of the overall system intelligence
  - Is more reusable
  - Is easier to implement
- A few, complex classes means that each class
  - Encapsulates a large portion of the overall system intelligence
  - Is less likely to be reusable
  - Is more difficult to implement

A class should have a single well-focused purpose.  
A class should do one thing and do it well!

# Strategies for Designing Boundary Classes

- User interface (UI) boundary classes
  - What user interface development tools will be used?
  - How much of the interface can be created by the development tool?
- External system interface boundary classes
  - Usually model as subsystem

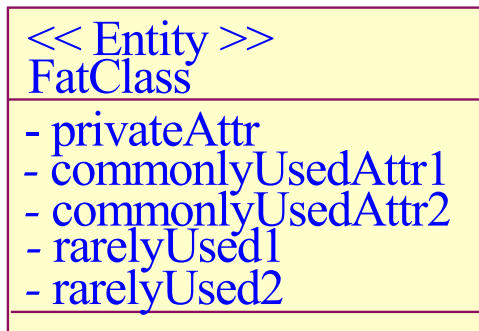

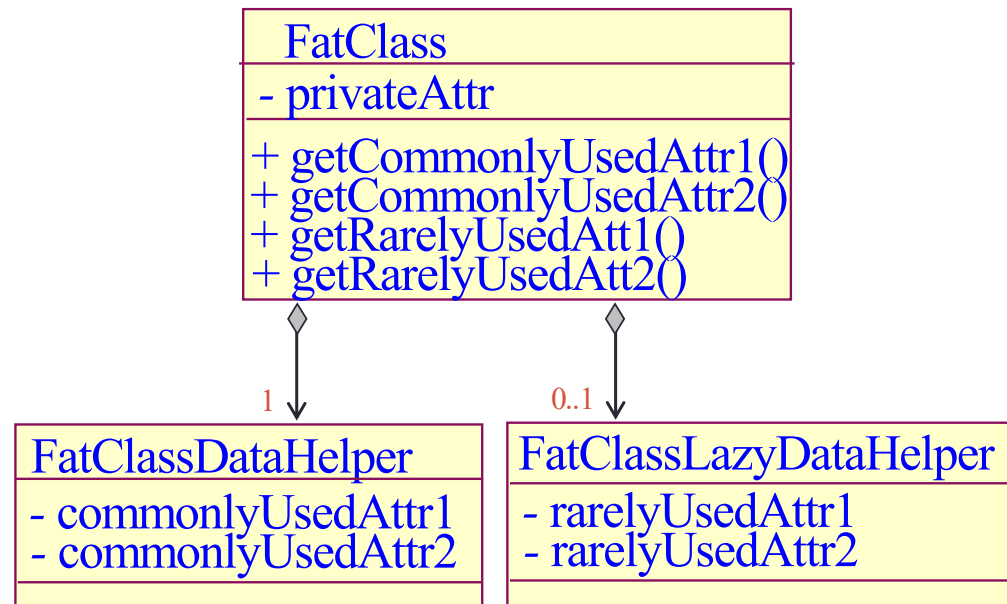

# Strategies for Designing Entity Classes

- Entity objects are often passive and persistent
- Performance requirements may force some re-factoring

## Analysis

## Design

## Strategies for Designing Control Classes

- What happens to Control Classes?
  - Are they really needed?
  - Should they be split?
- How do you decide?
  - Complexity
  - Change probability
  - Distribution and performance
  - Transaction management

# Review: Class and Package

- What is a class?
  - A description of a set of objects that share the same responsibilities, relationships, operations, attributes, and semantics

- What is a package?
  - A general purpose mechanism for organizing elements into groups
  - A model element which can contain other model elements

# Group Design Classes in Packages

- You can base your packaging criteria on a number of different factors, including:
  - Configuration units
  - Allocation of resources among development teams
  - Reflect the user types
  - Represent the existing products and services the system uses

# Packaging Tips: Boundary Classes

If it is **likely** the system interface will undergo considerable changes

Boundary classes placed in separate packages

If it is **unlikely** the system interface will undergo considerable changes

Boundary classes packaged with functionally related classes

## Packaging Tips:

# Functionally Related Classes

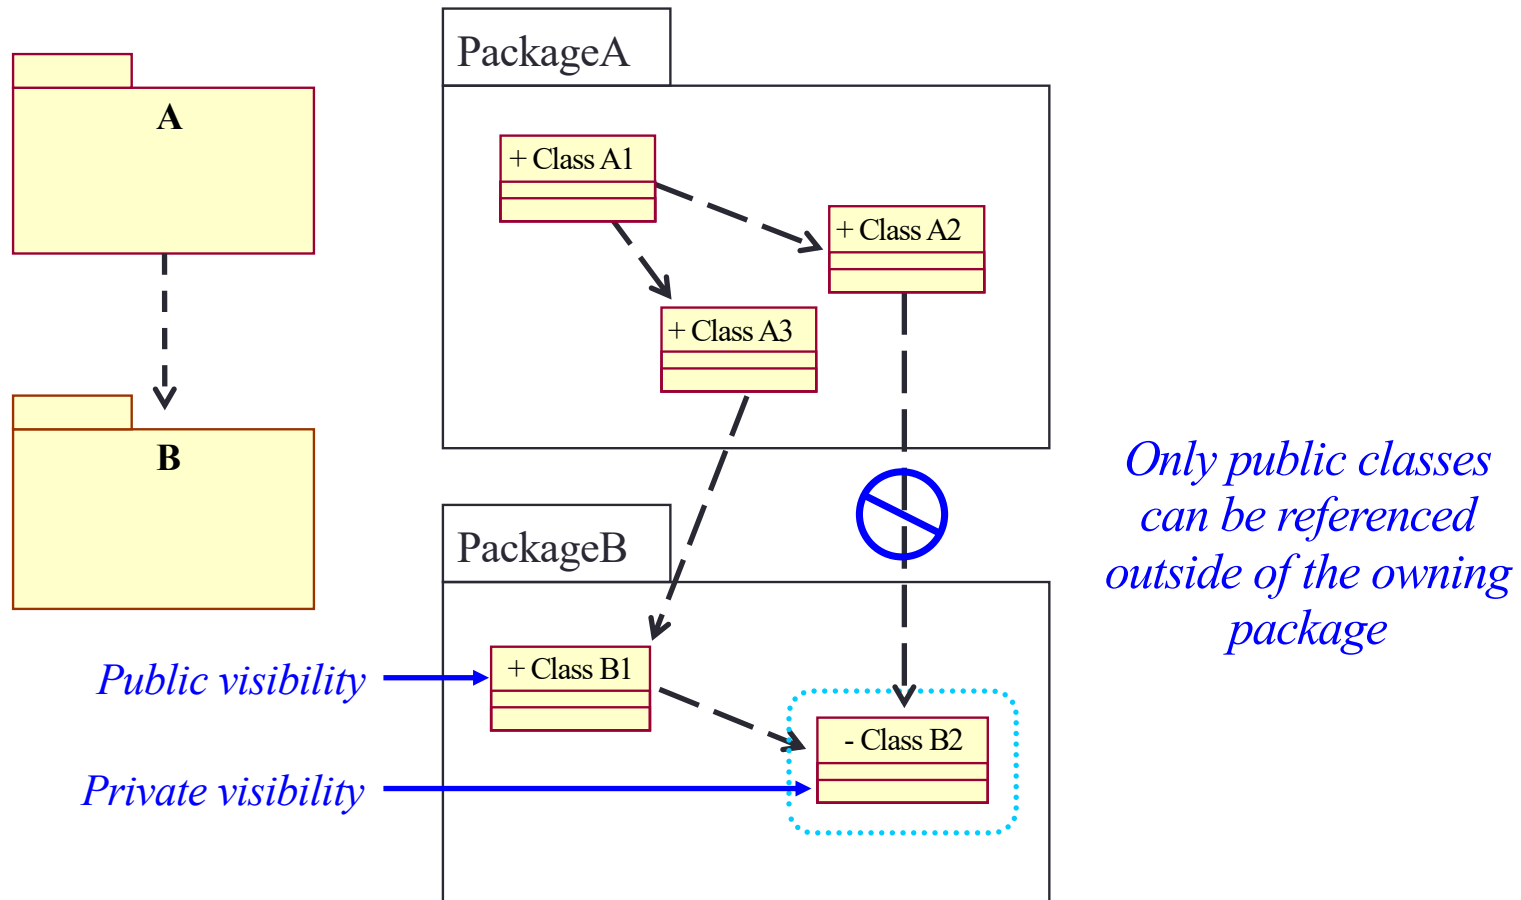

- Criteria for determining if classes are functionally related:
  - Changes in one class' behavior and/or structure necessitate changes in another class
  - Removal of one class impacts the other class
  - Two objects interact with a large number of messages or have a complex intercommunication
  - A boundary class can be functionally related to a particular entity class if the function of the boundary class is to present the entity class
  - Two classes interact with, or are affected by changes in the same actor

## Packaging Tips:

### Functionally Related Classes (continued)

- Criteria for determining if classes are functionally related (continued):
  - Two classes have relationships between each other
  - One class creates instances of another class
- Criteria for determining when two classes should **NOT** be placed in the same package:
  - Two classes that are related to different actors should not be placed in the same package
  - An optional and a mandatory class should not be placed in the same package

## Package Dependencies: Package Element Visibility

OO Principle: Encapsulation

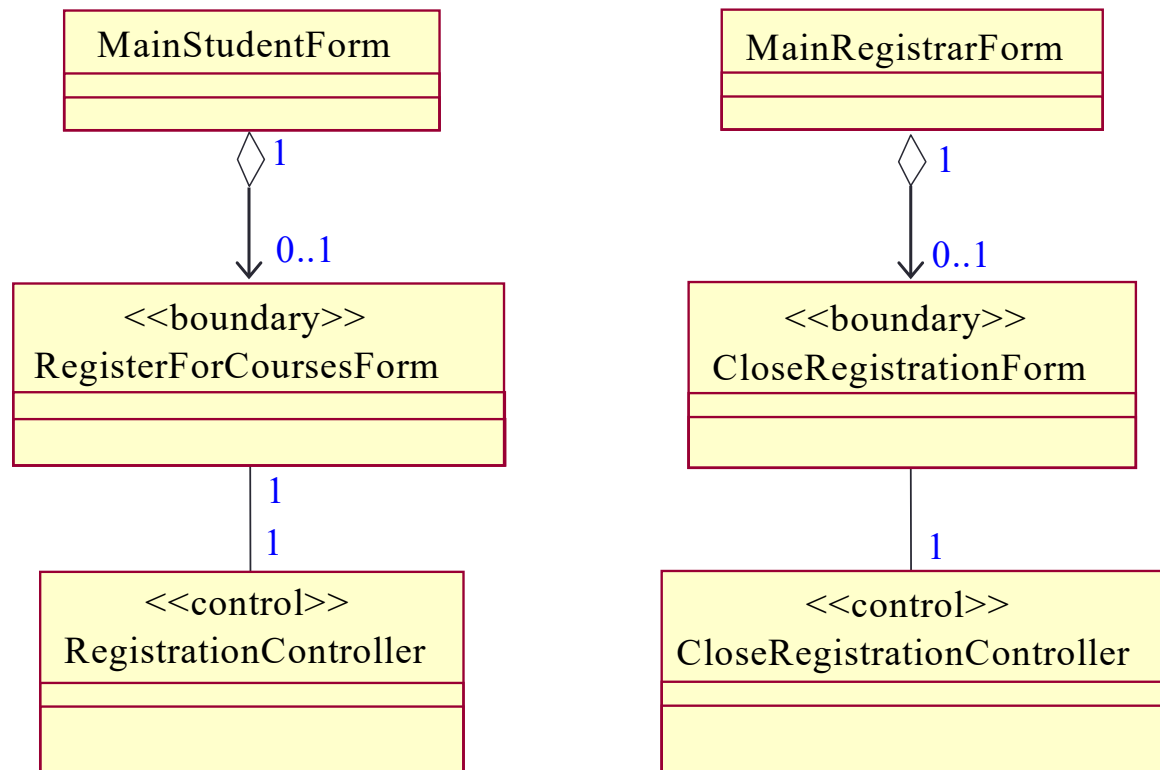

# Package Coupling: Tips

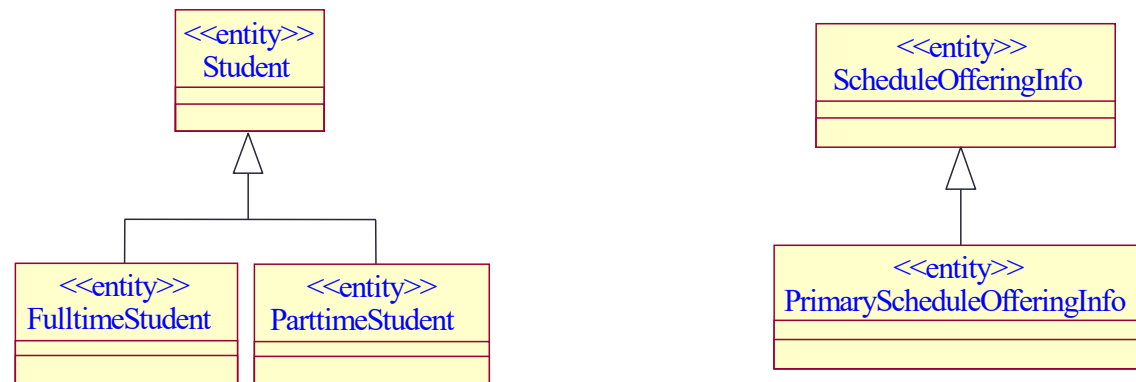

- Packages should not be cross-coupled
- Packages in lower layers should not be dependent upon packages in upper layers
- In general, dependencies should not skip layers

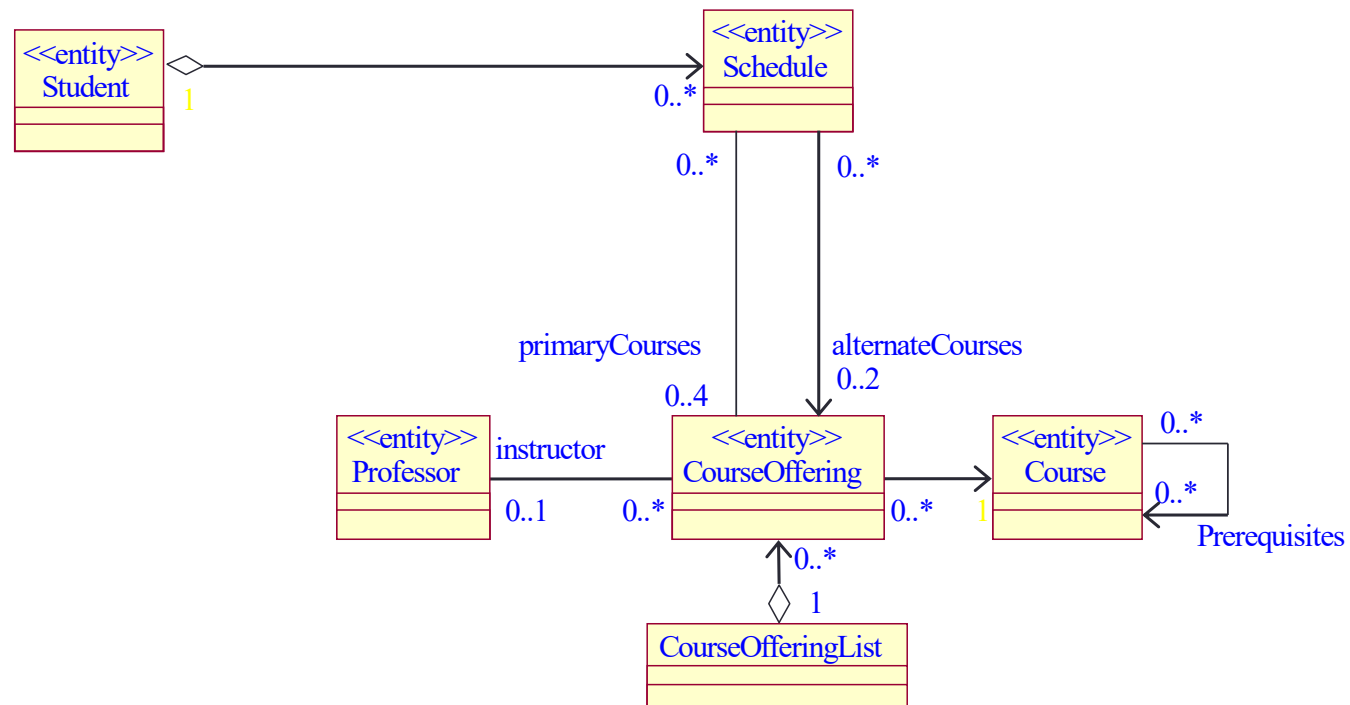

# Example: Registration Package

## Example: University Artifacts Package: Generalization

# Example: University Artifacts Package: Associations

## Example: External System Interfaces Package

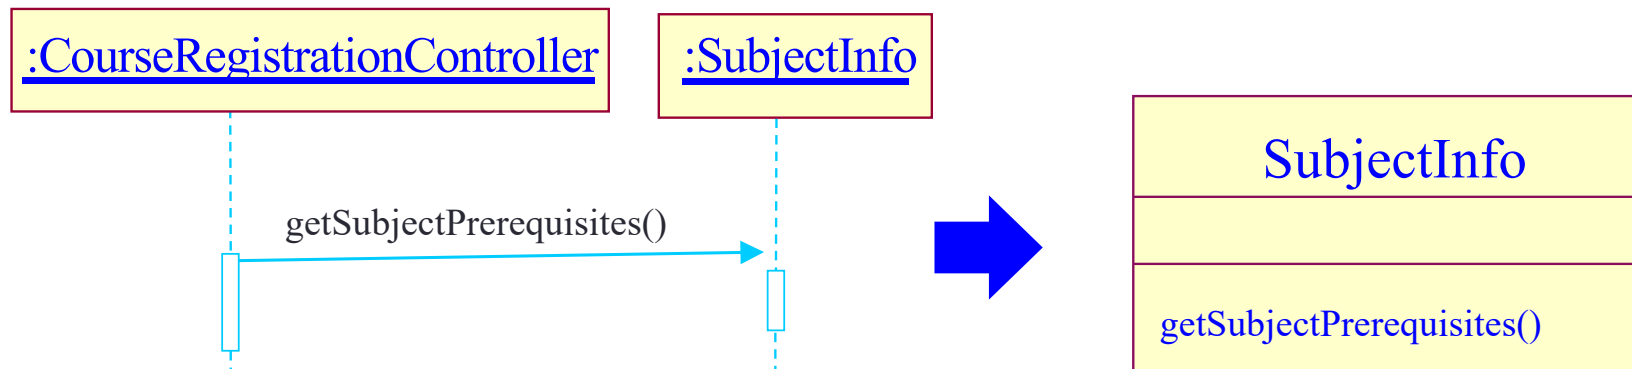

## Content

1. Create Initial Design Classes
- ➔ 2. Define Operations/Methods
3. Define Relationships Between Classes
4. Define States
5. Define Attributes
6. Class Diagram

## 2.1. Define Operations

- Messages displayed in interaction diagrams

- Other implementation dependent functionality
  - Manager functions
  - Need for class copies
  - Need to test for equality

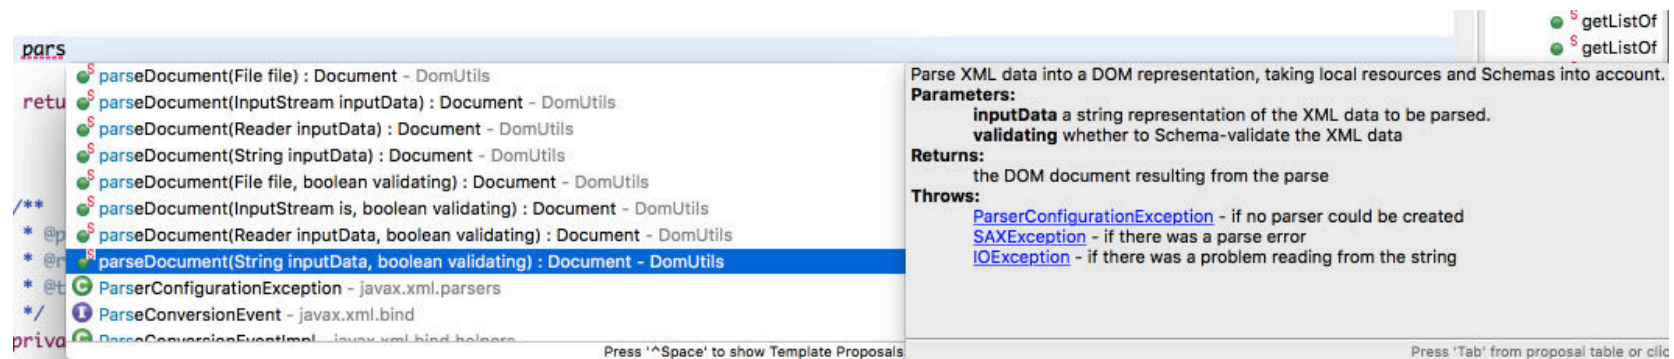

# Name and Describe the Operations

- Create appropriate operation names
  - Indicate the outcome
  - Use client perspective
  - Are consistent across classes
- Define operation signatures
  - `operationName([direction]parameter: class,...) : returnType`
    - Direction is **in** (default), **out** or **inout**
    - Provide short description, including meaning of all parameters

# Program documentation

```
/**
 * Parse XML data into a DOM representation, taking local resources and
 * Schemas into account.
 * @param inputData a string representation of the XML data to be parsed.
 * @param validating whether to Schema-validate the XML data
 * @return the DOM document resulting from the parse
 * @throws ParserConfigurationException if no parser could be created
 * @throws SAXException if there was a parse error
 * @throws IOException if there was a problem reading from the string
 */
public static Document parseDocument(String inputData, boolean validating)
throws ParserConfigurationException, SAXException, IOException {
    //Change to UnicodeReader for utf-8
    ...
}
```

## Guidelines: Designing Operation Signatures

- When designing operation signatures, consider if parameters are:
  - Passed by value or by reference
  - Changed by the operation
  - Optional
  - Set to default values
  - In valid parameter ranges
- The fewer the parameters, the better
- Pass objects instead of “data bits”

# Operation Visibility

- Visibility is used to enforce encapsulation
- May be public, protected, or private

# How Is Visibility Noted?

- The following symbols are used to specify export control:
  - + Public access
  - # Protected access
  - - Private access

Class1
- privateAttribute + publicAttribute # protectedAttribute
- privateOperation () + publicOperation () # protecteOperation ()

# Scope

- Determines number of instances of the attribute/operation
  - Instance: one instance for each class instance
  - Classifier: one instance for all class instances
- Classifier scope is denoted by underlining the attribute/operation name

Class1
- <u>classifierScopeAttr</u>
- instanceScopeAttr
+ <u>classifierScopeOp ()</u>
+ instanceScopeOp ()

## Course Registration CS: Operations for CourseInfo. and CourseRegistrationController

### CourseInfo

+ getCourseInfo(String): CourseInfo.

### CourseRegistrationController

+ registerForCourse(String, String): void  
- checkPrerequisiteCondition(): boolean  
- checkTimeAndSubjectConfliction(): boolean  
- checkCapacityConfliction(): boolean

## 2.2. Define Methods

- What is a method?
  - Describes operation implementation
- Purpose
  - Define special aspects of operation implementation
- Things to consider:
  - Special algorithms
  - Other objects and operations to be used
  - How attributes and parameters are to be implemented and used
  - How relationships are to be implemented and used

## Content

1. Create Initial Design Classes
2. Define Operations/Methods
- ➔ 3. Define Relationships Between Classes
4. Define States
5. Define Attributes
6. Class Diagram

# Class Relationships

- Association

- Aggregation

- Composition

- Inheritance

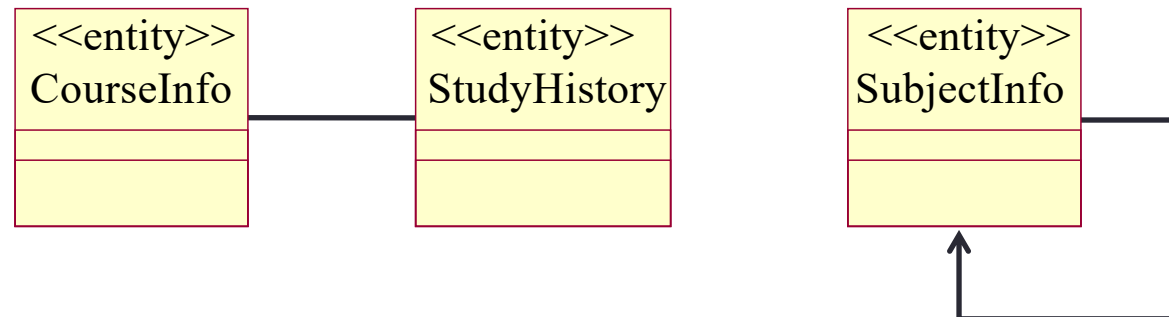

- Dependency

## 3.1. What is an Association?

- The semantic relationship between two or more classifiers that specifies connections among their instances
- A structural relationship, specifying that objects of one thing are connected to objects of another

# Finding Association

## Communication Diagram

*Link*

*Client*

*Supplier*

## Class Diagram

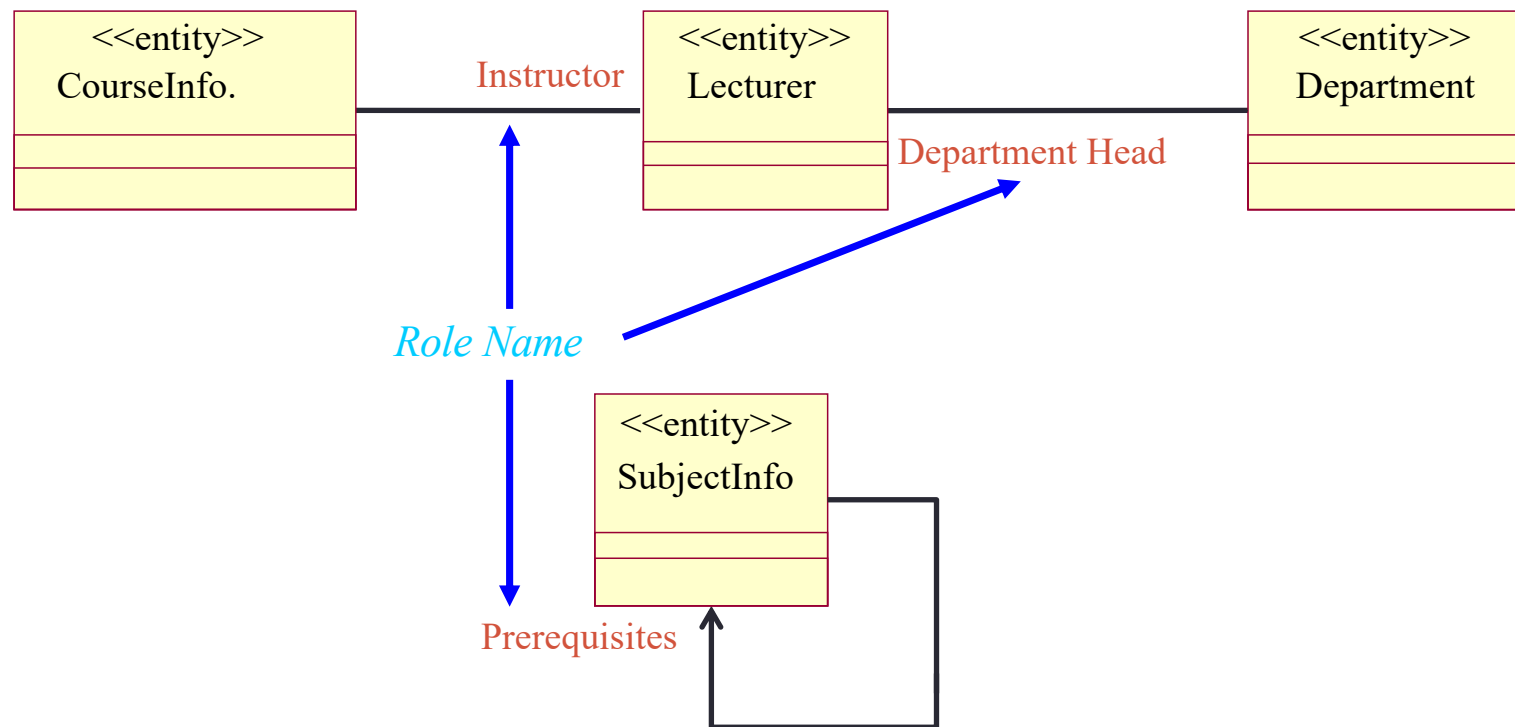

*Association*

Relationship for every link!

## 3.1.1. What Are Roles?

- The “face” that a class plays in the association

### 3.1.2. What Is Multiplicity?

- Multiplicity is the number of instances one class relates to ONE instance of another class.
- For each association, there are two multiplicity decisions to make, one for each end of the association.
  - For each instance of Professor, many Course Offerings may be taught.
  - For each instance of Course Offering, there may be either one or zero Professor as the instructor.

## Multiplicity Indicators

Unspecified	
Exactly One	1
Zero or More	0..*
Zero or More	*
One or More	1..*
Zero or One (optional value)	0..1
Specified Range	2..4
Multiple, Disjoint Ranges	2, 4..6

## What Does Multiplicity Mean?

- Multiplicity answers two questions:
  - Is the association mandatory or optional?
  - What is the minimum and maximum number of instances that can be linked to one instance?

## Java implementation

```

//InsuranceCompany.java file
public class InsuranceCompany
{
    // Many multiplicity can be implemented using Collection
    private List<InsuranceContract> contracts;

    /* Methods */
}
// InsuranceContract.java file
public class InsuranceContract
{
    private InsuranceCompany refers_to;

    /* Methods */
}
  
```

### 3.1.3. Association Types

- Association

- use-a

- Objects of one class are associated with objects of another class

- Aggregation

- has-a/is-a-part

- Strong association, an instance of one class is made up of instances of another class

- Composition

- Strong aggregation, the composed object can't be shared by other objects and dies with its composer
- Share life-time

## Review: What Is Aggregation?

- A special form of association that models a whole-part relationship between an aggregate (the whole) and its parts
  - An aggregation is an “is a part-of” relationship.
- Multiplicity is represented like other associations.

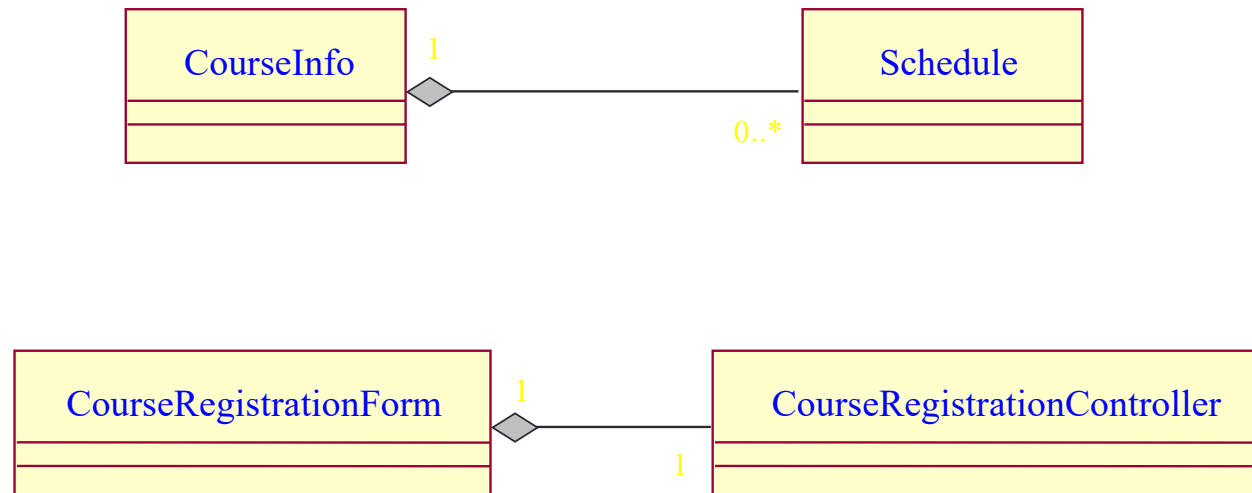

## Review: What is Composition?

- A special form of aggregation with strong ownership and coincident lifetimes of the part with the aggregate.
- The whole “owns” the part and is responsible for the creation and destruction of the part.
  - The part is removed when the whole is removed.
  - The part may be removed (by the whole) before the whole is removed.

## “Register for course” Use case

## Association or Aggregation?

- If two objects are tightly bound by a whole-part relationship
  - The relationship is an aggregation.

- If two objects are usually considered as independent, although they are often linked
  - The relationship is an association.

When in doubt, use association.

## Aggregation – Java implementation

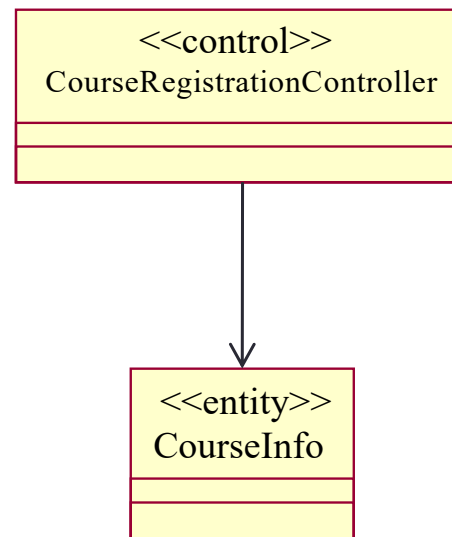

```
class Car {  
    private List<Door> doors;  
    Car(String name, List<Door> doors) {  
        this.doors = doors;  
    }  
  
    public List<Door> getDoors() {  
        return doors;  
    }  
}
```

# Composition – Java implementation

```
final class Car {  
    // For a car to move, it need to have a engine.  
    private final Engine engine; // Composition  
    //private Engine engine;      // Aggregation  
  
    Car(Engine engine) {  
        this.engine = engine;  
    }  
  
    // car start moving by starting engine  
    public void move() {  
        //if(engine != null)  
        {  
            engine.work();  
            System.out.println("Car is moving ");  
        }  
    }  
}  
  
class Engine {  
    // starting an engine  
    public void work() {  
        System.out.println("Engine of car has been started ");  
    }  
}
```

## 3.1.4. Navigability

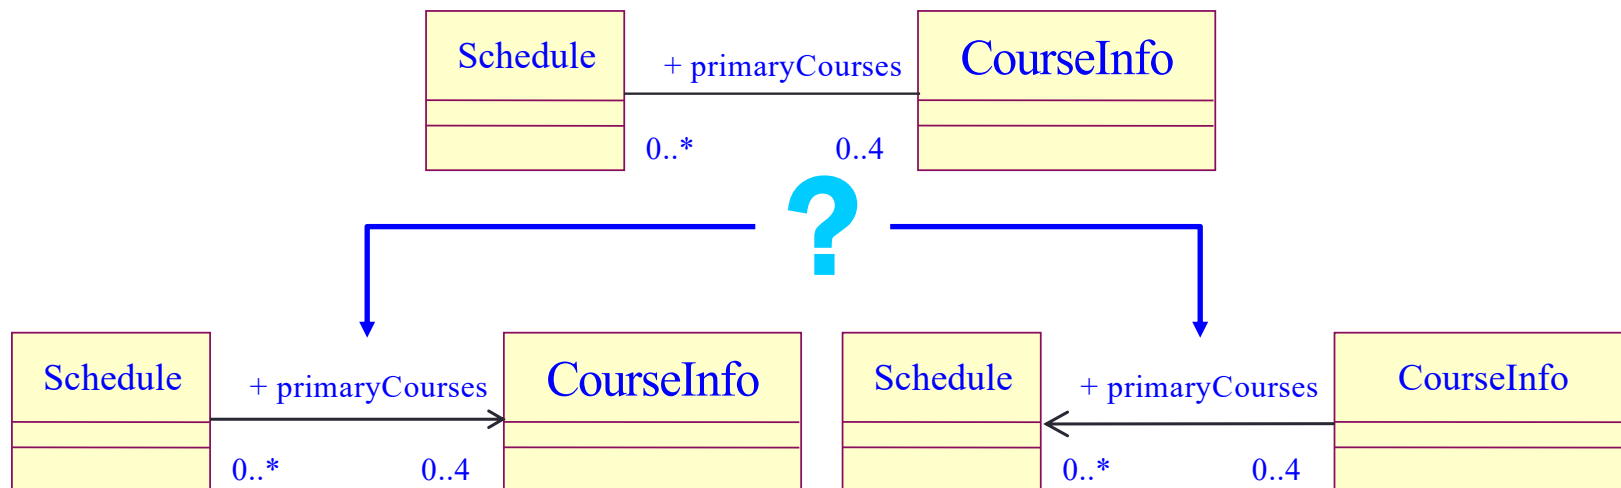

- Indicates that it is possible to navigate from an associating class to the target class using the association

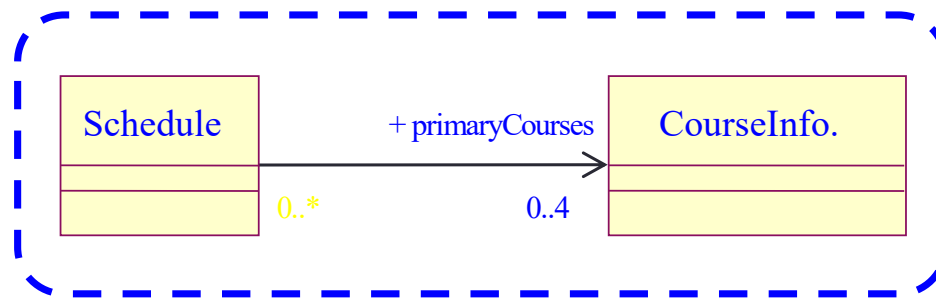

## Navigability: Which Directions Are Really Needed?

- Explore interaction diagrams
- Even when both directions seem required, one may work
  - Navigability in one direction is infrequent
  - Number of instances of one class is small

# Example: Navigability Refinement

- Total number of Schedules is small, or
- Never need a list of the Schedules on which the CourseInfo appears
- Total number of CourseInfo is small, or
- Never need a list of CourseInfo on a Schedule
- Total number of CourseInfo and Schedules are not small
- Must be able to navigate in both directions

## 3.2. Dependency

- What Is a Dependency?
  - A relationship between two objects

- Purpose
  - Determine where structural relationships are NOT required
- Things to look for :
  - What causes the supplier to be visible to the client

# Dependencies vs. Associations

- Associations are structural relationships
- Dependencies are non-structural relationships
- In order for objects to “know each other” they must be visible
  - Local variable reference
  - Parameter reference
  - Global reference
  - Field reference

## Associations vs. Dependencies in Collaborations

- An instance of an association is a link
  - All links become associations unless they have global, local, or parameter visibility
  - Relationships are context-dependent
- Dependencies are transient links with:
  - A limited duration
  - A context-independent relationship
  - A summary relationship

A dependency is a secondary type of relationship in that it doesn't tell you much about the relationship. For details you need to consult the collaborations.

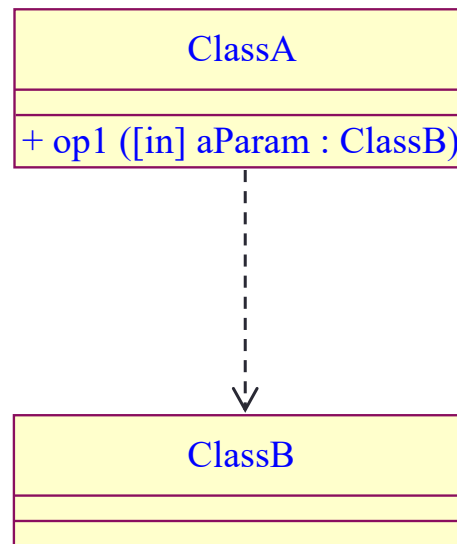

## 3.2.1. Local Variable Visibility

- The op1() operation contains a local variable of type ClassB

## 3.2.2. Parameter Visibility

- The ClassB instance is passed to the ClassA instance

### 3.2.3. Global Visibility

- The ClassUtility instance is visible because it is global

## Identifying Dependencies: Considerations

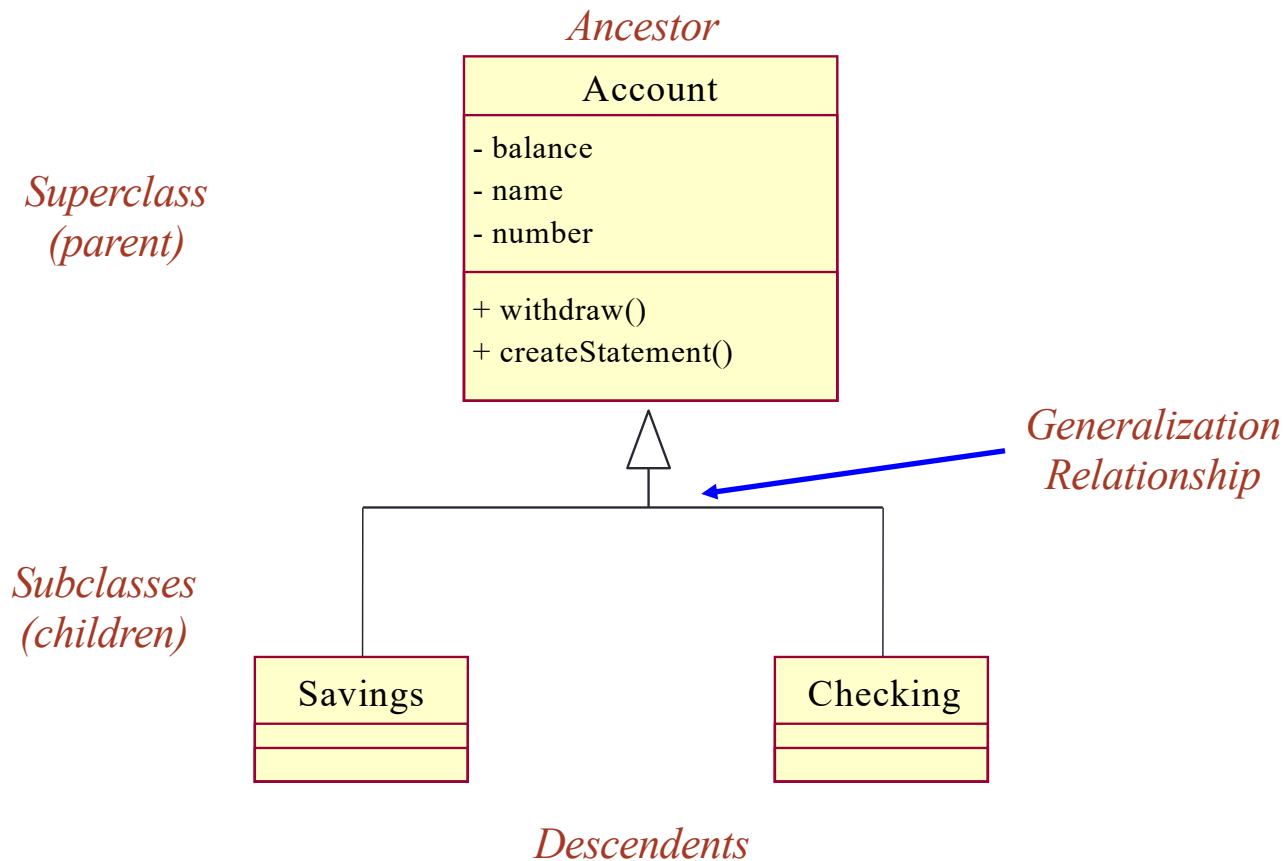

- Permanent relationships — Association (field visibility)
- Transient relationships — Dependency
  - Multiple objects share the same instance
    - Pass instance as a parameter (parameter visibility)
    - Make instance a managed global (global visibility)
  - Multiple objects don't share the same instance (local visibility)
- How long does it take to create/destroy?
  - Expensive? Use field, parameter, or global visibility
  - Strive for the lightest relationships possible

## 3.3. Generalization

- A relationship among classes where one class shares the structure and/or behavior of one or more classes.
- Defines a hierarchy of abstractions where a subclass inherits from one or more superclasses.
  - Single inheritance
  - Multiple inheritance
- Is an “is a kind of” relationship.

# Example: Single Inheritance

- One class inherits from another

# Content

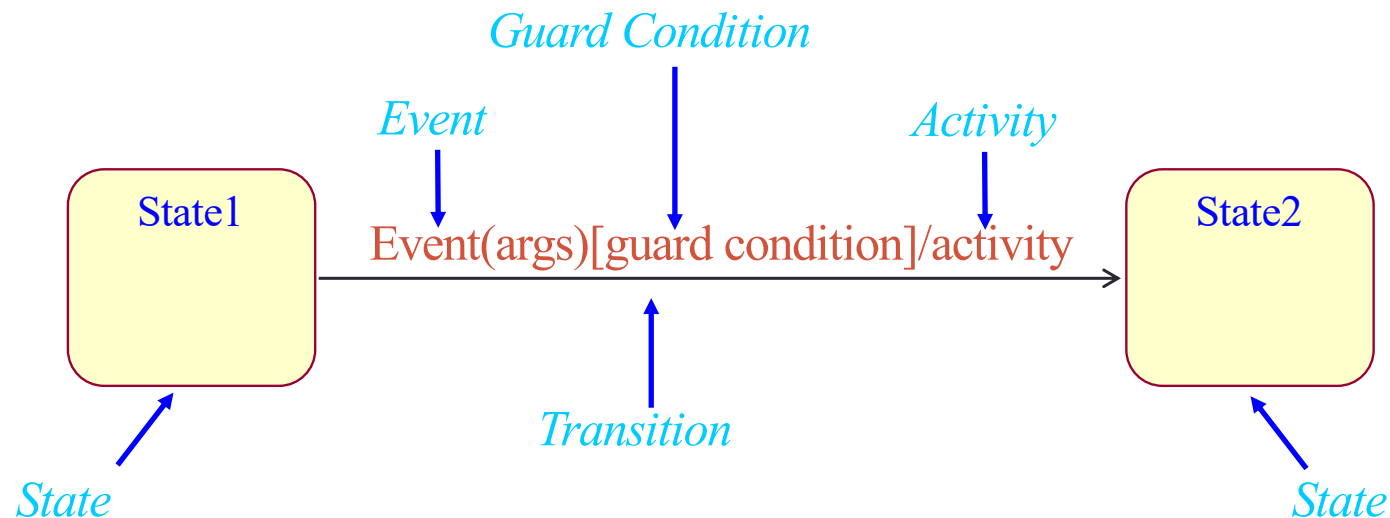

1. Create Initial Design Classes
2. Define Operations/Methods
3. Define Relationships Between Classes
- ➔ 4. Define States
5. Define Attributes
6. Class Diagram

## 4. Define States

- Purpose
  - Design how an object's state affects its behavior
  - Develop state machines to model this behavior
- Things to consider:
  - Which objects have significant state?
  - How to determine an object's possible states?
  - How do state machines map to the rest of the model?

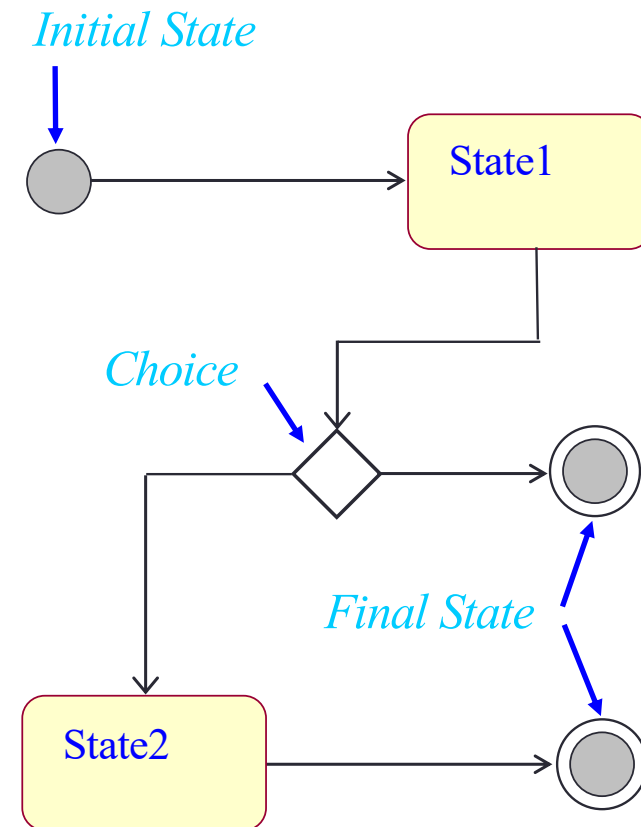

# What is a State Machine?

- A directed graph of states (nodes) connected by transitions (directed arcs)
- Describes the life history of a reactive object

# Pseudo States

- Initial state
  - The state entered when an object is created
  - Mandatory, can only have one initial state
- Choice
  - Dynamic evaluation of subsequent guard conditions
  - Only first segment has a trigger
- Final state
  - Indicates the object's end of life
  - Optional, may have more than one

# Identify and Define the States

- Significant, dynamic attributes

The minimum number of students per course is 3

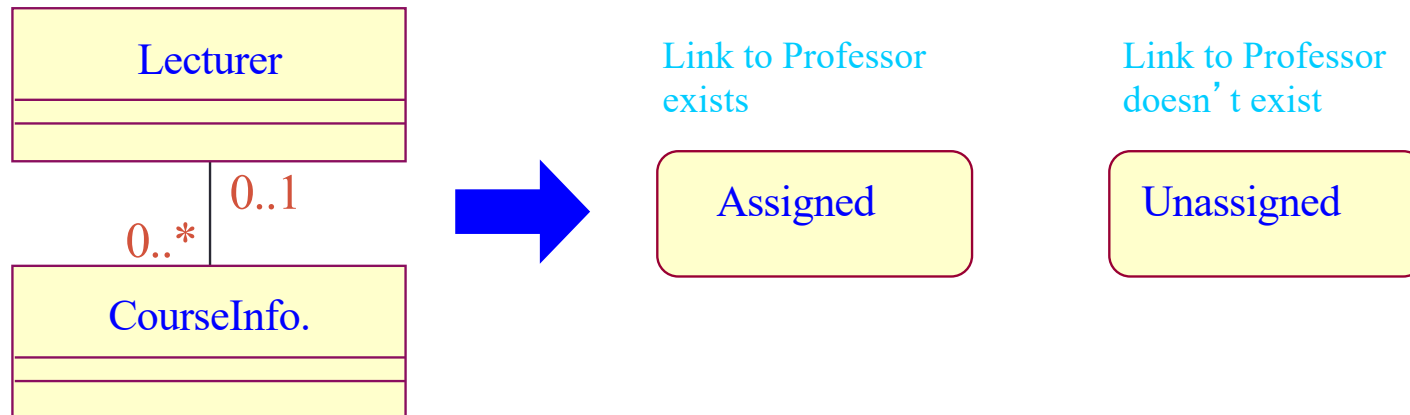

numStudents  $\geq 3$

Opened

numStudents  $< 3$

Closed

- Existence and non-existence of certain links

## Identify the Events

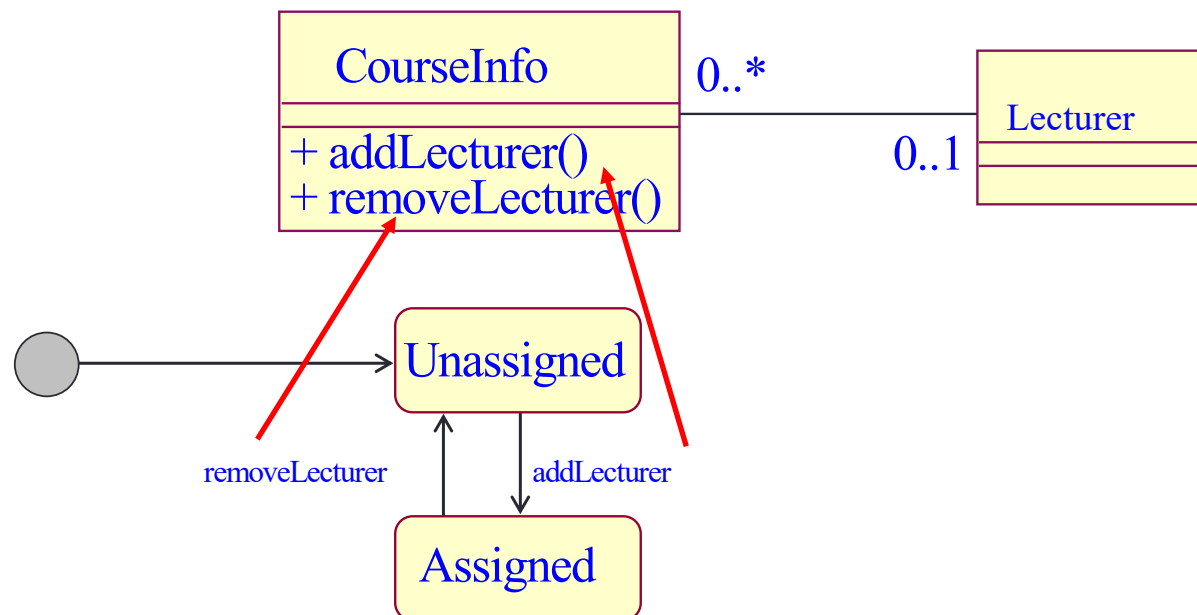

- Look at the class interface operations

Events: addLecturer,  
removeLecturer

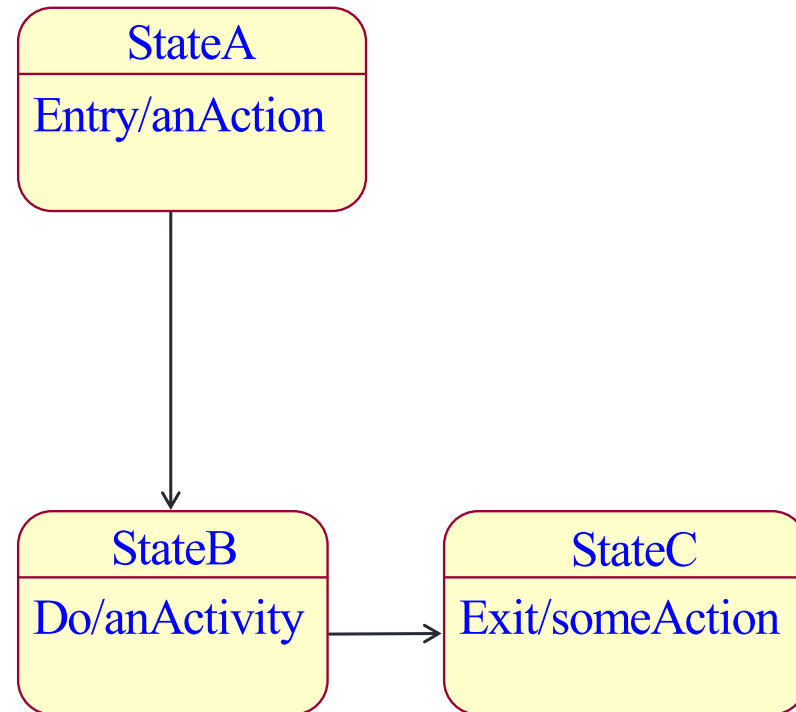

## Identify the Transitions

- For each state, determine what events cause transitions to what states, including guard conditions, when needed
- Transitions describe what happens in response to the receipt of an event

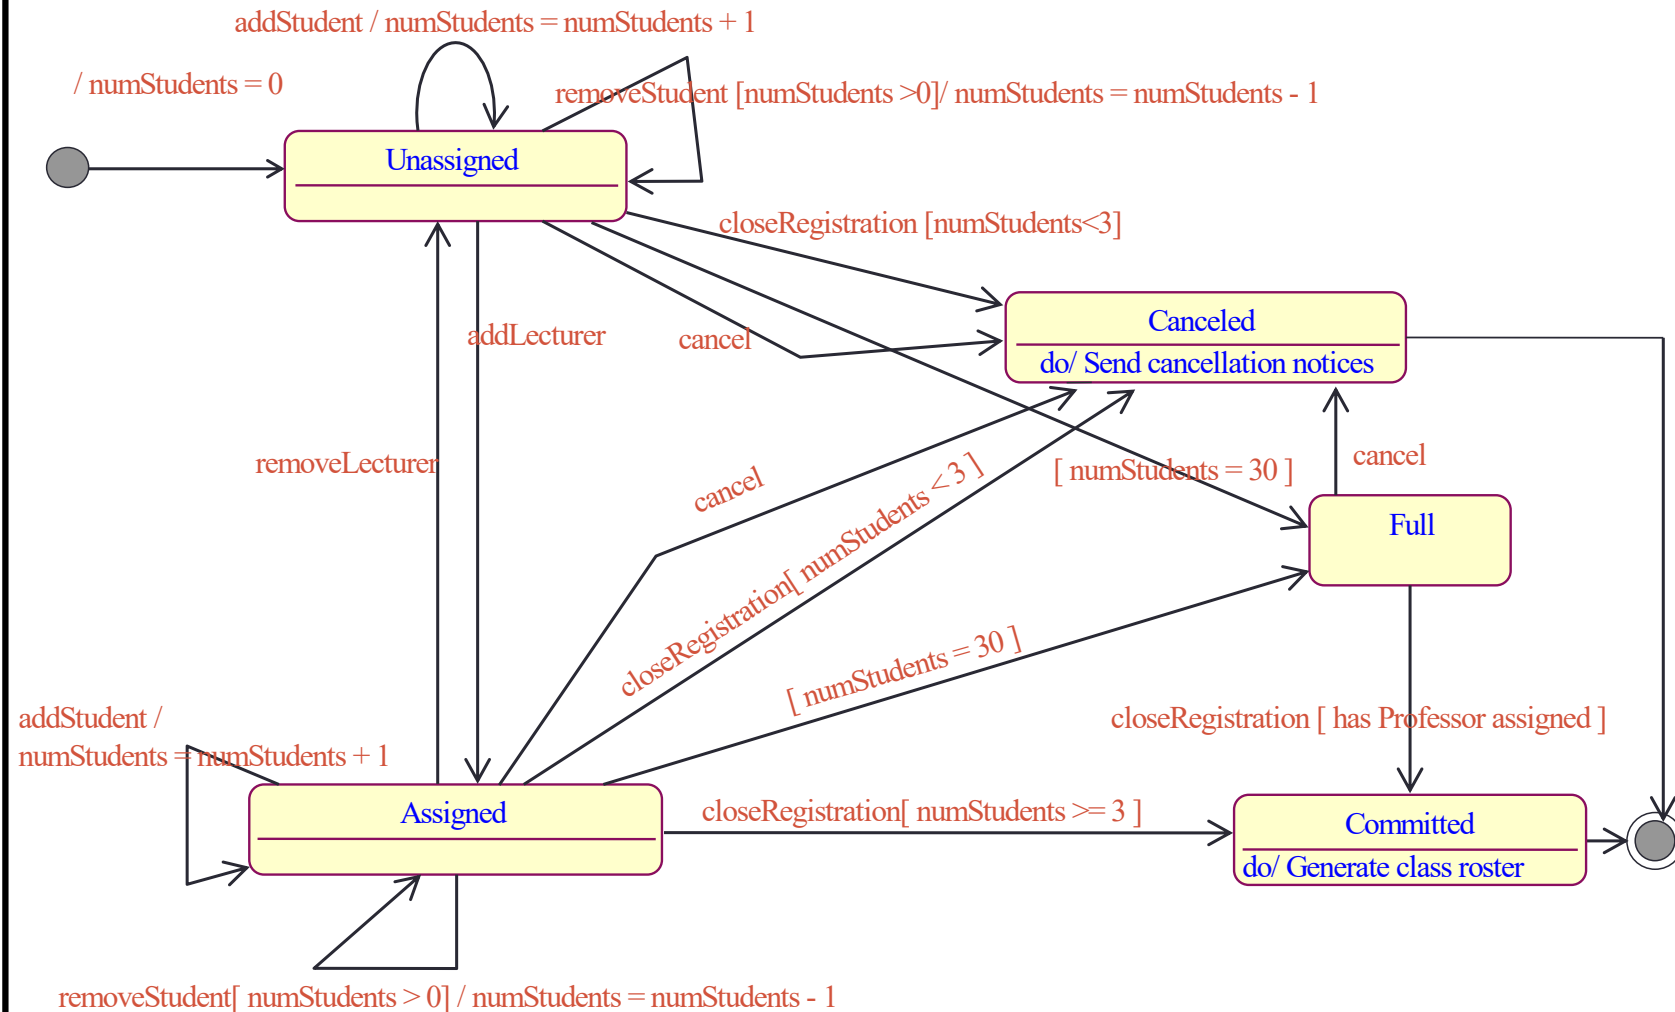

## Add Activities

- Entry
  - Executed when the state is entered
- Do
  - Ongoing execution
- Exit
  - Executed when the state is exited

# Example: State Machines

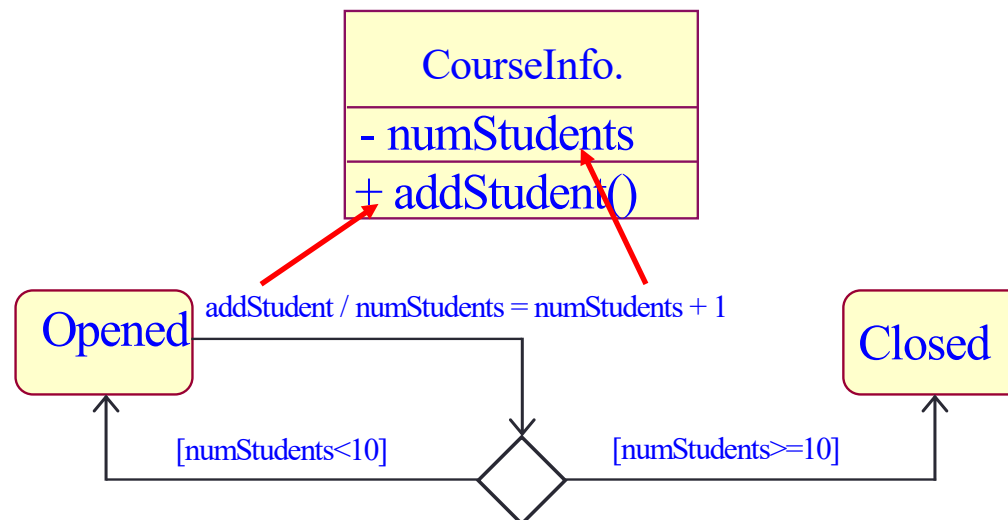

## Which Objects Have Significant State?

- Objects whose role is clarified by state transitions
- Complex use cases that are state-controlled
- It is not necessary to model objects such as:
  - Objects with straightforward mapping to implementation
  - Objects that are not state-controlled
  - Objects with only one computational state

## How Do State Machines Map to the Rest of the Model?

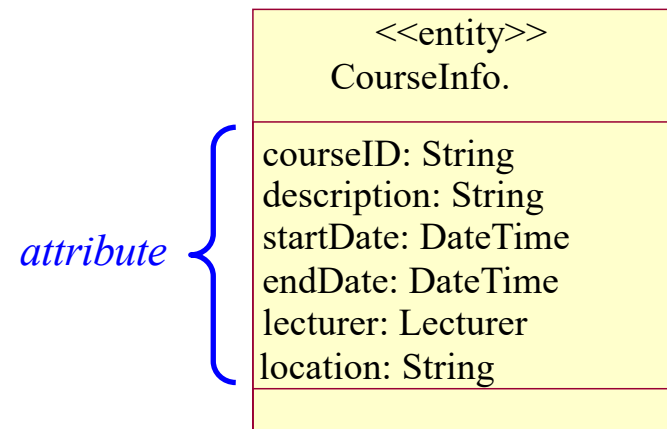

- Events may map to operations
- Methods should be updated with state-specific information
- States are often represented using attributes
  - This serves as input into the “*Define Attributes*” step

## Content

1. Create Initial Design Classes
2. Define Operations/Methods
3. Define Relationships Between Classes
4. Define States
- ➡ 5. Define Attributes
6. Class Diagram

# Review: What Is an Attribute?

## 5.1. Finding Attributes

- Properties/characteristics of identified classes
- Information retained by identified classes
- “Nouns” that did not become classes
  - Information whose value is the important thing
  - Information that is uniquely “owned” by an object
  - Information that has no behavior

## 5.1. Finding Attributes (2)

- Examine method descriptions
- Examine states
- Examine any information the class itself needs to maintain

## 5.2. Attribute Representations

- Specify name, type, and optional default value
  - `attributeName : Type = Default`
- Follow naming conventions of implementation language and project
- Type should be an elementary data type in implementation language
  - Built-in data type, user-defined data type, or user-defined class
- Specify visibility
  - Public: +                      Private: -                      Protected: #

## 5.3. Derived Attributes

- What is a derived attribute?
  - An attribute whose value may be calculated based on the value of other attribute(s)
- When do you use it?
  - When there is not enough time to re-calculate the value every time it is needed
  - When you must trade-off runtime performance versus memory required

## Example: Define Attributes

<<entity>>  
Schedule

- scheduleID: int
- day: String
- teachingPeriod: int

<<boundary>>  
CourseRegistrationForm

- courseID: String
- studentID: String

<<controll>>  
CourseRegistrationController

- courseID: String
- studentID: String

<<entity>>  
StudyHistory

- historyNo: int
- pass: boolean
- result: int
- studentID: String
- studentName: String

<<entity>>  
CourseInfo.

- courseID: String
- description: String
- startDate: DateTime
- endDate: DateTime
- lecturer: Lecturer
- location: String

<<entity>>  
SubjectInfo.

- subjectID: String
- subjectName: String
- goal: String
- description: String
- numberOfCredits: int

## Content

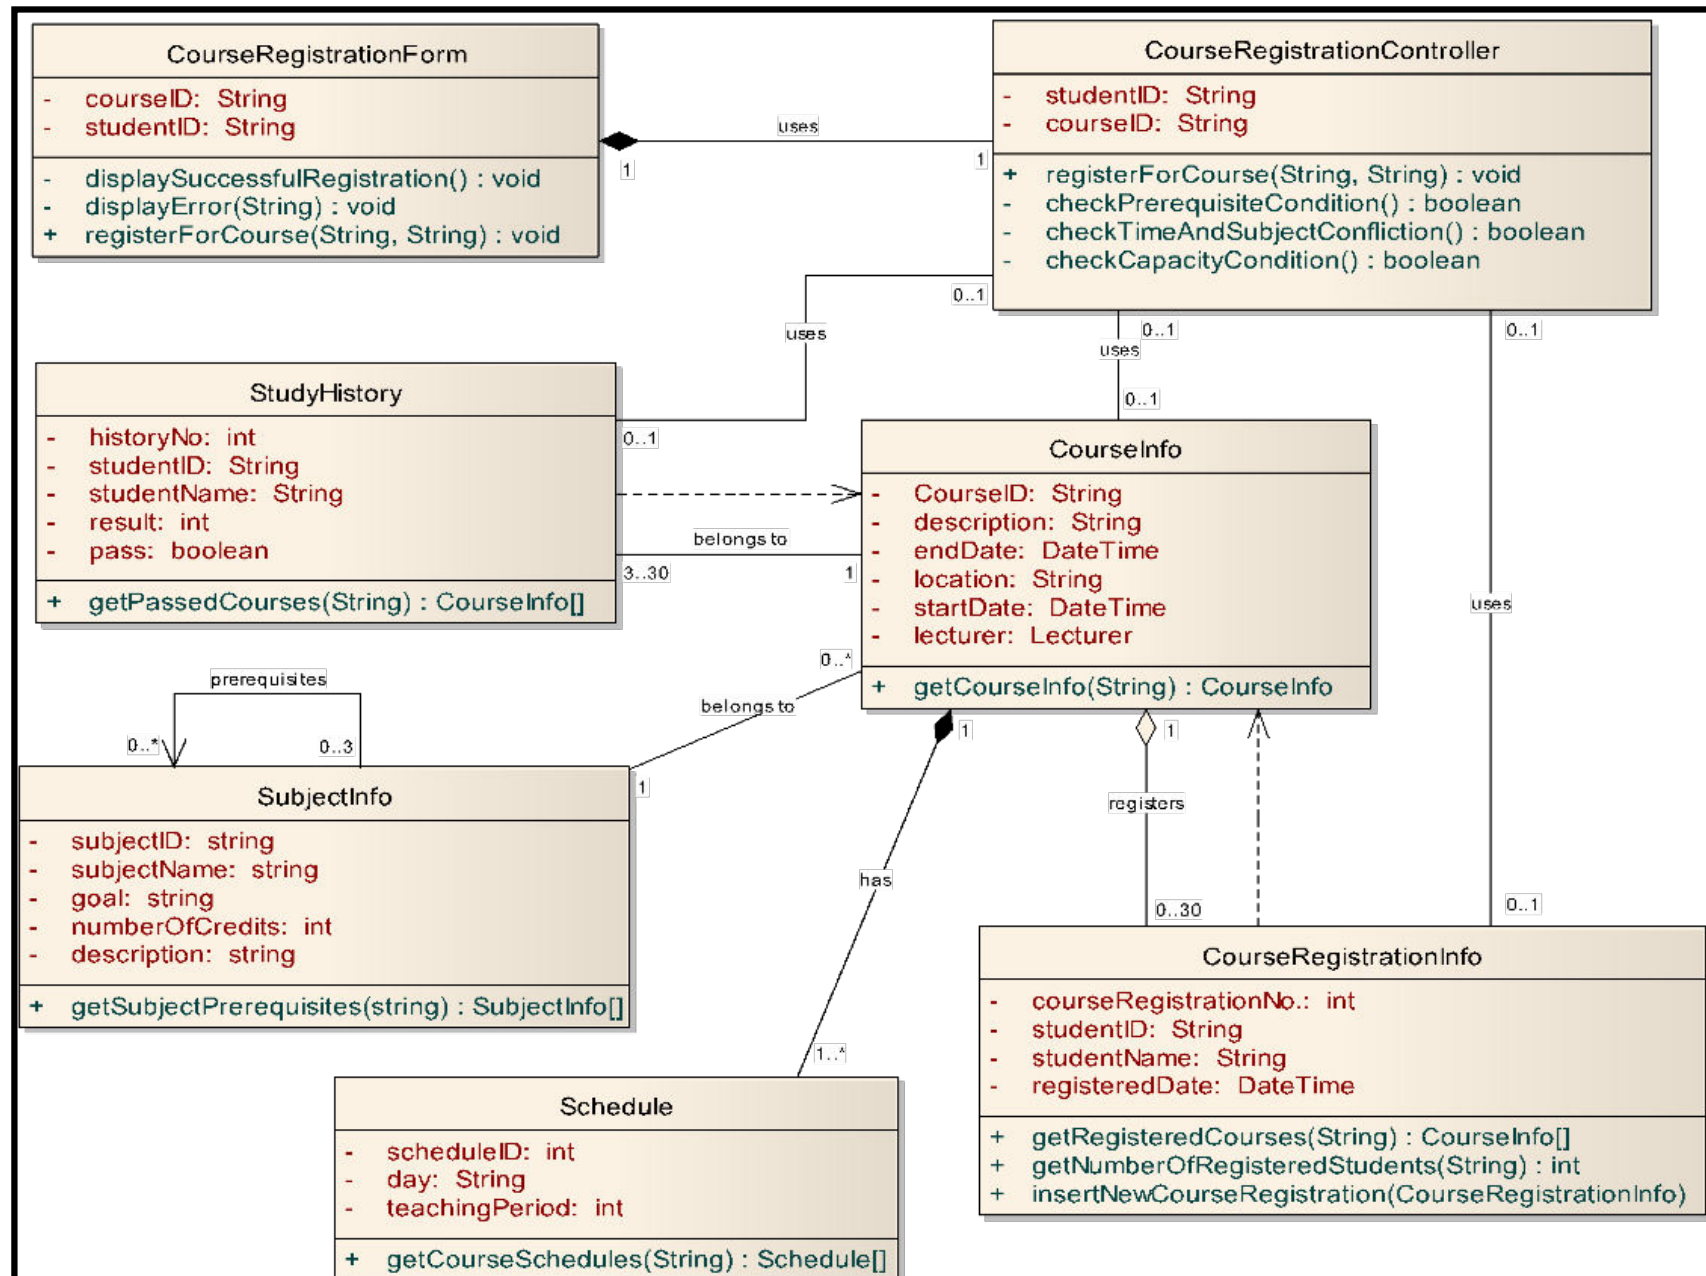

1. Create Initial Design Classes
2. Define Operations/Methods
3. Define Relationships Between Classes
4. Define States
5. Define Attributes

6. Class Diagram

## 6. Class diagram

- Static view of a system
- When modeling the static view of a system, class diagrams are typically used in one of three ways, to model:
  - The vocabulary of a system
  - Collaborations
  - A logical database schema

## Review: What Is a Package?

- A general purpose mechanism for organizing elements into groups.
- A model element that can contain other model elements.
- A package can be used:
  - To organize the model under development
  - As a unit of configuration management

## Review points: Classes

- Clear class names
- One well-defined abstraction
- Functionally coupled attributes/behavior
- Generalizations were made
- All class requirements were addressed
- Demands are consistent with state machines
- Complete class instance life cycle is described
- The class has the required behavior

## Review points: Operations

- Operations are easily understood
- State description is correct
- Required behavior is offered
- Parameters are defined correctly
- Messages are completely assigned operations
- Implementation specifications are correct
- Signatures conform to standards
- All operations are needed by Use-Case Realizations

## Review points: Attributes

- A single concept
- Descriptive names
- All attributes are needed by Use-Case Realizations

## Review points: Relationships

- Descriptive role names
- Correct multiplicities

Question?

# Class design

- Attribute design
  - Type, description
- Operation design
  - Operation Signature
  - Purpose/description of operation
  - Purpose /description of each parameter
  - Description of return value
  - Error/Exception (when)
- Method design
  - Special algorithm
  - How to use parameters

# Program documentation

```
/**
 * Parse XML data into a DOM representation, taking local resources and
 * Schemas into account.
 * @param inputData a string representation of the XML data to be parsed.
 * @param validating whether to Schema-validate the XML data
 * @return the DOM document resulting from the parse
 * @throws ParserConfigurationException if no parser could be created
 * @throws SAXException if there was a parse error
 * @throws IOException if there was a problem reading from the string
 */
public static Document parseDocument(String inputData, boolean validating)
throws ParserConfigurationException, SAXException, IOException {
    //Change to UnicodeReader for utf-8
    ...
}
```

The screenshot shows an IDE with a code completion menu for the `parseDocument` method. The menu lists several overloads, with the selected one being `parseDocument(String inputData, boolean validating) : Document - DomUtils`. To the right, a tooltip provides detailed documentation for this method.

**parseDocument(String inputData, boolean validating) : Document - DomUtils**

**Parameters:**

- inputData** a string representation of the XML data to be parsed.
- validating** whether to Schema-validate the XML data

**Returns:**

- the DOM document resulting from the parse

**Throws:**

- [ParserConfigurationException](#) - if no parser could be created
- [SAXException](#) - if there was a parse error
- [IOException](#) - if there was a problem reading from the string
